*Taxonomy Alfisols In The Semi Arid*

Alfisols form in semi-arid to humid areas, typically under a hardwood forest cover. They have a clay-enriched subsoil and relatively high native fertility. "Alf" refers to aluminium (Al) and iron (Fe). Because of their productivity and abundance, the Alfisols represent one of the more important soil orders for food and fiber production.

In the semi arid tropics Vertisol, Alfisols, and soils related to Alfisols account for 14.54 million km<sup>2</sup>, or 69% of the land area. These soils are usually phosphate deficient. The phosphate that does exist is chemically bound with iron, calcium or aluminum.

## 2. THE PROBLEM OF AGRICULTURE IN THE SEMI-ARID REGIONS

Alfisols are important soils in the semi-arid tropics (SAT), covering nearly 33% of the SAT region. With their poor water retention characteristics, rainfed crop- ping of Alfisols is ever threatened with deficient soil moisture conditions even in relatively short dry spells.

Abstract. Alfisols are the third most important soil order in the world, covering 13.1% of the world area. In the semi-arid tropics, Alfisols cover a much larger area of potentially arable and grazable lands than Vertisols, which have until now received far more attention from ICRISAT researchers.

Nonconventional Annual Cropping Systems Some success with minimum tillage land-use systems has been reported on Alfisols in the semi-arid tropics (Perrier (1983). Off-season tillage serves several useful purposes (Vijaylakshmi
